Scripts for Hack5 tools

About device

USB Rubber Ducky

USB Rubber Ducky is a popular hacking tool developed by Hack5. Designed to appear as a harmless USB flash drive, in reality functions as a **Human Interface Device (HID)**.

By tricking the computer to recognise it as a keyboard, it allows for rapid keystroke injection attacks, or automation of mundane repetitive tasks.

About script

Stealing files using USB Rubber Ducky

The script targets machines using Windows operating system.

The main feature of the script is stealthily copying encrypted pdf files from selected directory onto the USB Rubber Ducky.

There are three components:

- payload.txt (DuckyScript)
- payload.ps1 (powershell script)
- target.txt

1. Preparation

When you plug in USB Rubber Ducky it starts as normal storage device. You can now specify the target directory using **target.txt** file. If there is no such file or path inside the file is invalid the script will target **Downloads** directory of the active user.

To start the script you need to push the button underneath the Rubber Ducky case.

2. Execution

Upon activation Rubber Ducky will open run window, start powershell in the background and load previously prepared **payload.ps1**. Firstly the script will create a directory on the Rubber Ducky with the name of the machine. Secondly it will look for encrypted pdf files within the target directory and copy them into previously prepared directory.

3. Clean-up

The script will erase the history of recently accessed files and programs open through run window.

When everything is done it will turn **CAPSLOCK** key on and off three times to signal that you can safely remove Rubber Ducky.

Demonstration
